Dashboard Report

Story Description

After Covid-19 and Military Dictatorship, my body weights are not under control due to stress and unsystematic lifestyles. From this, my body weight steadily rise up to 170 and I started exercising in a Functional Fitness Studio in my hometown. At that time, I experienced the difficulty to lose weights steadily like other members. After controlling the calories intake, the weights decreases to 165. At 2024, I relocated to Yangon to expand my learning and to connect with my friends, when I stopped workouts and lost calories intake control. That was the start of my PCOS symptom that I experienced whole month menstrual cycle for months. Plus, the inflammation and other side effects happen at the same. I came back to hometown at 2025 to do the workout again and to manage my nutritions. That technique works to have regular menstrual cycle and regular metabolism system even though I have stubborn weight.

Key findings

1=> The data found doing exercise is a tool to control PCOS intensity regardless of weights. This is because the PCOS symptom and irregular menstrual cycle getting worse when I stopped exercise at 2024 and the PCOS system rise up to 10/10 scale.

2=> The importance of overall Mood and Hours of sleep to have regular menstrual cycle and to escape weight trajectory. In 2024, the sleep hours was low and mood average was also low around 2-5 over 10. Therefore, my body weights goes up and my menstrual cycle is irregular.

3=> Last but not least, the insights found the body weights cannot influence the PCOS because in terms of my data, I was able to reduce my PCOS level through workout and enough sleep regardless of stubborn weights.

Decision-making explanation

Based on the data trends displayed across the 61-month tracking analysis, the decision-making framework changed from treating body weight as a primary metric to focusing on internal wellbeing (healthy lifestyle and Fitness). The line graphs and stacked bar distributions revealed a distinct independence between total body mass, which remained on a stubborn weight between 178 lbs and 184 lbs throughout 2025 and 2026, despite overall symptomatic control of PCOS. The dashboard proved that reintroducing consistent functional training and structured nutritional protocols directly suppressed the subjective PCOS severity index from a crisis peak of 10.0 down to a manageable 4.0. Besides through the identification of a critical threshold in the scatter plot where sleep durations below 6.0 hours caused mood indicators to drive below a score of 4.0, these visualizations provided the empirical justification to establish a strict 7-to 8 hours nightly sleep window, actively neutralizing cortisol-driven inflammation and shifting health management toward sustainable, and metabolic recovery.

Ethical discussion

The dashboard is manually created base on my memory throughout the PCOS journey. So, the data can be wrong and not be exact. Besides, I did include the medication data and blood test data that I needed to do to diagnosis the PCOS with Professional OG and Nutritionist Data. Therefore, the findings may incorrect or need validation to have a true decision based on my data. Since, this is my personal journey of weight gain, PCOS and recovery, the recovery progress for other people who also have PCOS, may differ from each's metabolism system, lifestyles and past heath conditions. For example, the intensity of workout can have negative effects on the other people who have the other health problems. Overall, my dashboard cannot fully reflect how to cure PCOS system and cannot guarantee the robustness of the data insights due to the lack of important factors to make a conclusion of PCOS symptom.
